Introduction to Algorithms

Topic 3 : Comparison Based Sorting Algorithms

Xiang-Yang Li and Haisheng Tan[1]

School of Computer Science and Technology
University of Science and Technology of China (USTC)

Fall Semester 2022

Outline

Basic Concepts

Simple Sorting Algorithms

Efficient Sorting Algorithms

Summary

Basic Concepts of Sorting Algorithm

Stability

Regardless of how the input data is distributed, the data objects of the same keyword will be kept in the same order as in the input during the sorting process, which is called *stable sorting*. Otherwise, called *unstable sorting*.

Example: $2, 2^*, 1 \rightarrow 1, 2^*, 2$ (unstable sorting)

Time Complexity

Usually measured by the number of data **comparisons** and the number of data **movements** in the algorithm execution.

In-place Sorting

only a constant of elements are stored outside the input array.

Insertion Sort

General idea: Maintain an ordered sequence.
INSERTION-SORT(A)

1: **for** $j = 2$ to $A.length$ **do**
2:     $key = A[j]$
3:     // Insert $A[j]$ into the sorted sequence $A[1..j-1]$.
4:     $i = j - 1$
5:     **while** $i > 0$ and $A[i] > key$ **do**
6:         $A[i+1] = A[i]$
7:         $i = i - 1$
8:     $A[i+1] = key$

Shellsort

General idea:

- ▶ Choose a descending gap sequence (*e.g., $D = [5, 3, 2, 1]$*).
- ▶ In each round, elements with the same gap d are in the same group.
- ▶ Apply INSERTION-SORT for each group.
- ▶ Reduce the amount of data migration that caused by insertion sort.

Efficient Sorting Algorithms
Summary

Shellsort
Heapsort
Quicksort

Shellsort

Shellsort
Why Shellsort typically performs faster?

- Insertion-Sorting small-sized array although costs $O(n^2)$ in the worst case, but it is similar to $O(n)$ in values.
- For large array, when we use a gap large enough (in the order of $O(n)$), each sub-array has a small size, thus efficient to sort.
- After enough iterations, when the gap is small, the majority part of the array is already sorted (thus the complexity is small again).

Outline
Basic Concepts
Simple Sorting Algorithms
Efficient Sorting Algorithms
Summary

Shellsort
Heapsort
Quicksort

Shellsort

How to select the gap sequence?

- $\lceil \frac{n}{2^k} \rceil$: time complexity $\Theta(n^2)$

- $2\lceil \frac{n}{2^{k+1}} \rceil + 1$: time complexity $\Theta(n^{\frac{3}{2}})$

- $2^k - 1$: time complexity $\Theta(n^{\frac{3}{2}})$

- $2^k + 1$ ($k \geq 0$): time complexity $\Theta(n^{\frac{3}{2}})$

- Successive numbers of the form $2^p 3^q$ for prime numbers p, q: time complexity $\Theta(n \log^2 n)$.

Simple Sorting Algorithms
Efficient Sorting Algorithms
Summary

Shellsort
Heapsort
Quicksort

Shellsort: the lowerbound on the time-complexity

The worst-case complexity of any version of Shellsort is of higher order: Plaxton, Poonen, and Suel showed that it grows at least as rapidly as $\Omega\left(n\left(\dfrac{\log n}{\log\log n}\right)^2\right)$.

Basic Concepts of Heap

Heap

A data structure which is an array object that can be viewed as a **nearly complete binary tree**.

The tree is completely filled on all levels except possibly the lowest, which is filled from the left up to a point.

Given the index i of a node, the indices of its parent $\text{PARENT}(i)$, left child $\text{LEFT}(i)$, and right child $\text{RIGHT}(i)$ can be computed simply:

$$
\begin{array}{lll}
\text{PARENT}(i) & \textbf{return} & \lfloor i/2 \rfloor \\
\text{LEFT}(i) & \textbf{return} & 2*i \\
\text{RIGHT}(i) & \textbf{return} & 2*i+1
\end{array}
$$

Shellsort
Heapsort
Quicksort
Maintaining the Heap Property

Assumption: sub-trees rooted at $\text{LEFT}(i)$ & $\text{RIGHT}(i)$ are max-heaps.

$\text{MAX-HEAPIFY}(A, i)$ // Input an an array and an index i

1: $l = \text{LEFT}(i)$;
2: $r = \text{RIGHT}(i)$
3: **if** $l \leq A.heap\text{-}size$ and $A[l] > A[i]$ **then**
4:     $largest = l$
5: **else** $largest = i$
6: **if** $r \leq A.heap\text{-}size$ and $A[r] > A[largest]$ **then**
7:     $largest = r$
8: **if** $largest \neq i$ **then**
9:     $A[i] \leftrightarrow A[largest]$
10:     $\text{MAX-HEAPIFY}(A, largest)$

Quicksort
Building a Heap

Fact: with the array representation of an n-element heap, the leaves are the nodes indexed from $\lfloor A.length/2 \rfloor + 1$ to n, and each leaf is a 1-element max-heap to begin with.

BUILD-MAX-HEAP(A)
1: $A.heap\text{-}size = A.length$
2: **for** $i = \lfloor A.length/2 \rfloor$ downto 1 **do**
3:     MAX-HEAPIFY(A, i)

Priority Queues

A ***priority queue*** is a data structure for maintaining a set S of elements, each with an associated value called a ***key***. A ***max-priority queue*** supports the following operations:

- INSERT(S, x) inserts the element x into the set S, which is equivalent to the operation $S = S \cup \{x\}$.

- MAXIMUM(S) returns the element of S with the largest key.

- EXTRACT-MAX(S) removes and returns the element of S with the largest key.

- INCREASE-KEY(S, x, k) increases the value of element x's key to the new value k, which is assumed to be at least as large as x's current key value.

Performance of Quicksort

Worst-case partitioning

The worst-case behavior for quicksort occurs when the partitioning routine produces one subproblem with $n-1$ **elements and one with** 0 **elements**. The partitioning costs $\Theta(n)$ time. the recurrence for the running time is

$$
\begin{aligned}
T(n) &= T(n-1) + T(0) + \Theta(n) \\
&= T(n-1) + \Theta(n) \\
&= \Theta(n^2).
\end{aligned}
$$

Outline
Basic Concepts
Simple Sorting Algorithms
Efficient Sorting Algorithms
Summary

Shellsort
Heapsort
Quicksort

Performance of Quicksort

Best-case partitioning

In the most even possible split, PARTITION produces two subproblems, each of size no more than $n/2$, since **one is of size $\lfloor n/2 \rfloor$ and one of size $\lceil n/2 \rceil - 1$**. In this case, quicksort runs much faster. The recurrence for the running time is then

$$T(n) = 2T(n/2) + \Theta(n)$$
$$= \Theta(n \lg n).$$

Outline
Basic Concepts
Simple Sorting Algorithms
Efficient Sorting Algorithms
Summary

Shellsort
Heapsort
Quicksort

Performance of Quicksort

Balanced partitioning

What if the split is always $\frac{1}{10} : \frac{9}{10}$? The recurrence for the running time is

$$T(n) = T(\frac{1}{10}n) + T(\frac{9}{10}n) + \Theta(n)$$
$$= \Theta(n \lg n).$$

Analysis of Quicksort

Worst-case analysis

We saw that a worst-case split at every level of recursion in quicksort produces a $\Theta(n^2)$ running time, which, intuitively, is the worst-case running time of the algorithm.

Using the **substitution method** (see Section 4.3), we can show that the running time of quicksort is $O(n^2)$.

Shellsort
Heapsort
Quicksort

Analysis of Quicksort

Let $T(n)$ be the worst-case time for the procedure QUICKSORT on an input of size n. We have

$$
\begin{aligned}
T(n) &= \max_{0 \le q \le n-1} (T(q) + T(n-q-1)) + \Theta(n) \\
&\le \max_{0 \le q \le n-1} (cq^2 + c(n-q-1)^2 + \Theta(n)) \\
&= c \cdot \max_{0 \le q \le n-1} (q^2 + (n-q-1)^2 + \Theta(n)) \\
&\le cn^2 - c(2n-1) + \Theta(n) \le cn^2.
\end{aligned}
$$

Quicksort

Analysis of Quicksort

Running time and comparisons

Rename the elements of the array A as $z_1, z_2, ..., z_n$, with z_i being the ith smallest element (assuming distinct elements).

$Z_{ij} = \{z_i, z_{i+1}, ..., z_j\}$ to be the set of elements between z_i and z_j.

We define

$$X_{ij} = I\{z_i \text{ is compared to } z_j\}.$$

Since each pair is compared at most once, we can easily characterize **the total number of comparisons** performed by the algorithm:

$$X = \sum_{i=1}^{n-1} \sum_{j=i+1}^{n} X_{ij}.$$

Analysis of Quicksort

$$E[X] = E\left[\sum_{i=1}^{n-1}\sum_{j=i+1}^{n} X_{ij}\right] = \sum_{i=1}^{n-1}\sum_{j=i+1}^{n} E[X_{ij}]$$

$$= \sum_{i=1}^{n-1}\sum_{j=i+1}^{n} Pr\{z_i \text{ is compared to } z_j\}$$

z_i与z_j何时会被比较一次？
——z_i/z_j被选作piviot时（否则将永远分开）
